# SCHAEFFLER

# **Planetary Screw Drives**

### Foreword

Due to the increasing demand for subassemblies and systems, the use of ready-to-fit linear systems as economically innovative machine components is becoming increasingly important. On this basis, Schaeffler has developed series comprising planetary screw drives and the matching bearing components for the locating and non-locating bearing side of the spindle bearing arrangement.

Planetary screw drives convert a rotational motion into a translational motion. Due to the high performance density and the very high axial load carrying capacity, they are extremely suitable as drives for actuators and open up the possibility of replacing hydraulic or pneumatic drives. As a result, the requirement for energy savings and conservation of resources can be fulfilled by the use of electromechanical drive systems. There is significant potential for savings in this case.

Due to the high conversion ratio of planetary screw drives, high axial forces can be achieved with low drive torques and without a gearbox. In addition to the cost-effective motors possible as a result, the long rating life and low maintenance requirements of the planetary screw drives give a highly economical drive system.

For advice on the selection and application of planetary screw drives and the preparation of design proposals, please contact the skilled personnel in Application Engineering and our engineering service both at home and abroad.

# Load carrying capacity and life

| Requirements              | <ul> <li>In order to determine the requisite size of a planetary screw drive, the requirements for the following criteria must be taken into consideration:</li> <li>load carrying capacity</li> <li>rating life</li> <li>operational reliability.</li> <li>The load carrying capacity is indicated in the dimensioning of the planetary screw drive by the basic load ratings given in the dimension tables.</li> </ul> |
|---------------------------|--|
| Basic dynamic load rating | The basic dynamic load rating C corresponds to a purely axial,<br>constant load under which 90% of a sufficiently large number<br>of apparently identical planetary screw drives reach or exceed<br>a basic rating life of 1 million revolutions.  |
| Basic static load rating  | The basic static load rating $C_0$ describes the force acting concentri-<br>cally and constantly in an axial direction under which the Hertzian<br>pressure between the threaded rollers and the spindle at the most<br>heavily loaded point induces a permanent overall deformation<br>of 0,0001 times the flank diameter of a threaded roller. In this case,<br>the Hertzian pressure is 4 200 N/mm <sup>2</sup> .     |
| Operating temperature     | Planetary screw drives can be used at operating temperatures from $-10$ °C to +100 °C.   |

# **Basic rating life** The basic rating life L<sub>10</sub> and L<sub>10h</sub> is reached or exceeded by 90% of a sufficiently large number of apparently identical bearings before the first evidence of rolling fatigue occurs:

The basic rating life for a displacement distance of 10<sup>5</sup> m,  

$$L_{10} = \left(\frac{C}{P_a}\right)^3$$

$$L_{10h} = \frac{16666}{n_m} \cdot \left(\frac{C}{P_a}\right)^3$$

$$L_{10h} = \frac{8,33 \cdot P}{H \cdot n_{osc}} \cdot \left(\frac{C}{P_a}\right)^3$$

$$L_{10h} = \frac{8,33 \cdot P}{H \cdot n_{osc}} \cdot \left(\frac{C}{P_a}\right)^3$$

$$L_{10} = \frac{100}{H \cdot n_{osc}} \cdot \left(\frac{C$$

ļ

In design, it must be ensured that the equivalent axial bearing load does not exceed the value  $P_a = 0.5 \cdot C$ . If it exceeds this value, please consult Schaeffler.

## Load carrying capacity and life

### Equivalent load and speed

The equations for calculating the basic rating life assume that the load and speed are constant. Non-constant operating conditions can be taken into consideration by means of equivalent operating values. These have the same effect as the loads occurring in practice.

If the load and speed vary in steps over a time period T, Figure 1, n<sub>m</sub> and P<sub>a</sub> are calculated as follows:

$$n_{m} = \frac{q_{1} \cdot n_{1} + q_{2} \cdot n_{2} + \dots + q_{z} \cdot n_{z}}{100}$$

$$P_{a} = \sqrt[3]{\frac{q_{1} \cdot n_{1} \cdot F_{1}^{3} + q_{2} \cdot n_{2} \cdot F_{2}^{3} + \dots + q_{z} \cdot n_{z} \cdot F_{z}^{3}}{q_{1} \cdot n_{1} + q_{2} \cdot n_{2} + \dots + q_{z} \cdot n_{z}}}_{i}$$

$$n_{m} \qquad \min^{-1}$$
Equivalent speed
$$q_{i} \qquad \%$$

Time proportion of an operating mode relative to the total operating period;

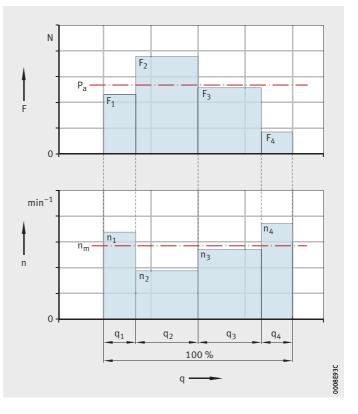

$$\begin{array}{ll} q_i = (\Delta t_i / T) \cdot 100 \\ n_i & \mbox{min}^{-1} \\ \mbox{Constant speed during the time period i} \\ P_a & \mbox{N} \end{array}$$

Equivalent axial load

r E

r

Ν Fi Constant load during the time period i.

Figure 1 Load and speed varying in steps

### Static load safety factor

The static load safety factor  $S_0$  is the security against permanent deformation at the rolling contact:

$$S_0 = \frac{C_0}{F_0}$$

 $\begin{array}{ccc} S_0 & - \\ Static load safety factor \\ C_0 & N \\ Basic static load rating \\ F_0 & N \\ Maximum axial force. \end{array}$ 

The static load safety factor  ${\rm S}_0$  should not be less than the value 4. If this is the case, however, please consult Schaeffler.

### Operating life

The operating life is defined as the life actually achieved by the planetary screw drive. It may differ significantly from the basic, calculated life.

Possible causes of premature failure due to wear or fatigue include: excessive loads as a result of misalignments

- contamination
- inadequate lubrication
- oscillating motion with very small swivel angles
- vibration while stationary
- overloading of the planetary screw drive (even for short periods)
- plastic deformation.

## Lubrication

Planetary screw drives must be lubricated.

The lubricant operating life or the relubrication interval respectively are essentially dependent on:

- load
- velocity
- stroke length
- environmental conditions.

### Initial greasing

Planetary screw drives are supplied with a preservative. Prior to commissioning, they must be lubricated using the specified initial grease quantity.

### Initial grease quantity

The initial grease quantity is made up of several components, see table.

| [                | Determining |
|------------------|-------------|
| the initial grea | se quantity |

| Nominal diameter | Initial grease quantity |            |                        |
|------------------|-------------------------|------------|------------------------|
| d <sub>0</sub>   | Static                  | Moving     |                        |
|                  |                         | Base value | Dependent<br>on stroke |
| mm               | g                       | g          | g/100 mm               |
| 5                | 2,8                     | 0,7        | 0,4                    |
| 9                | 3                       | 0,8        | 0,6                    |
| 12               | 4,2                     | 1,1        | 0,8                    |
| 15               | 4,1                     | 1          | 1                      |
| 20               | 4,8                     | 1,2        | 1,2                    |
| 25               | 7,2                     | 1,8        | 1,6                    |

The lubrication quantities are introduced partially while the nut is static and partially while it is moving.

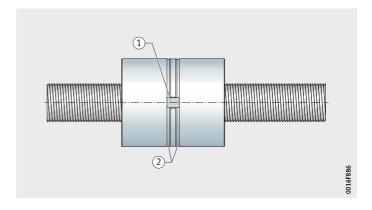

Since the nut in the planetary screw drive does not have contact seals, a portion of the grease is carried out of the nut over the stroke range. In order to take account of this process, the grease quantity is increased during initial greasing and regreasing by an amount as a function of the stroke.

Example Planetary screw drive PWG09 with a stroke of 100 mm:

initial grease quantity = 3 g + 0.8 g + 0.6 g = 4.4 g

- Of this amount:
  - 3 g is introduced while the nut is stationary
  - 0,8 g + 0,6 g is introduced while the nut is moved over its complete stroke.

# **Lubricant feed** Lubricant feed is carried out in the central area of the nut. The lubricant is fed into the interior via the grooves on the circumference of the nut halves, *Figure 1*.

Position for lubricant feed
 Integrated lubrication grooves

*Figure 1* Lubricant feed

**Recommended greases** 

Since the planetary screw drive is operated in the mixed friction range, we recommend lithium soap or lithium complex soap greases with a mineral oil base, EP additives and solid lubricant components

The locating bore in the housing must not have a circumferential

to a positional error of the supplied spacer.

ISO VG 150 for the base oil.

lubrication groove in the central area of the nut, since this can lead

that fulfil the conditions for greases in accordance with DIN 51825-KPF2K–20. We recommend grease lubrication using greases of NLGI grade 2 and

## Lubrication

**Grease operating life** Since it is not possible to calculate all the influencing factors, the precise grease operating life can only be determined under operating conditions. The approximation equation below, however, can be used to determine a guide value for many applications:

$$\mathbf{t}_{\mathrm{fG}} = \mathbf{t}_{\mathrm{f}} \cdot \mathbf{K}_{\mathrm{P}} \cdot \mathbf{K}_{\mathrm{W}} \cdot \mathbf{K}_{\mathrm{U}}$$

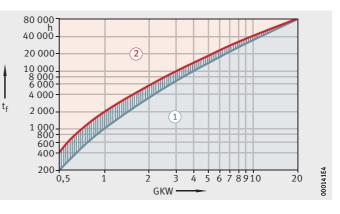

t<sub>fG</sub> h Guide value for grease operating life in operating hours t<sub>f</sub> h Basic lubrication interval in operating hours

 $K_{P}$ ,  $K_{W}$ ,  $K_{U}$  – Correction factors for load, stroke and environment.

The grease operating life is restricted, due to the ageing resistance of the grease, to a maximum of 3 years.

The basic lubrication interval  $t_f$ , *Figure 2*, is valid under the following conditions:

- bearing temperature < +70 °C</p>
- load ratio  $C_0/P = 20$
- no disruptive environmental influences
- stroke ratio between 10 and 50, see page 12.

t<sub>f</sub> = basic lubrication interval GKW = speed parameter

**Basic lubrication interval** 

Relubrication possible
 Regreasing necessary

Figure 2 Determining the basic lubrication interval **Speed parameter** In order to determine the basic lubrication interval, the speed parameter must be known.

The speed parameter is calculated as follows:

$$\mathsf{GKW} = \frac{60}{\overline{\mathsf{v}}} \cdot \mathsf{K}_{\mathsf{LF}}$$

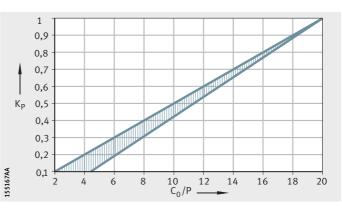

### **Correction factors**

Correction factor for load K<sub>P</sub>

The correction factor  $K_P$  takes account of the strain on the grease at a load ratio of  $C_0/P < 20$ , Figure 3.

The correction factors take account of the influences of load, stroke and environment on the grease operating life.

The factors are only valid for high quality lithium soap greases.

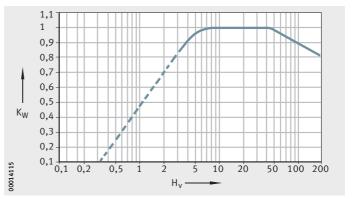

$$\label{eq:Kp} \begin{split} K_{P} &= \text{correction factor for load} \\ C_{0}/P &= \text{load ratio} \end{split}$$

*Figure 3* Correction factor for load

## Lubrication

# $\begin{array}{c} \text{Correction factor} \\ \text{for stroke length } K_W \end{array}$

The correction factor  $K_W$  takes account of the displacement distance to be lubricated, *Figure 4*. It is dependent on the stroke ratio.

 $K_W$  = correction factor for stroke length  $H_v$  = stroke ratio

Figure 4 Correction factor for stroke length

Stroke ratio

If the stroke ratio  $\rm H_V$  is less than 10 or more than 50, the grease operating life is reduced due to the risk of fretting corrosion or loss of grease.

The stroke ratio is calculated as follows:

If the stroke length is very short, the grease operating life may be shorter than the calculated guide value. In this case, special greases are recommended; please consult Schaeffler.

The correction factor  $K_{\rm U}$  takes account of shaking forces, vibrations (a cause of fretting corrosion) and shocks, see table.

These influences place an additional strain on the grease.

If cooling lubricant or moisture enters the system, calculation is not possible.

| d<br>r | Environmental influence | Correction factor<br>K <sub>U</sub> |
|--------|-------------------------|-------------------------------------|
|        | Slight                  | 1                                   |
|        | Moderate                | 0,8                                 |
|        | Heavy                   | 0,5                                 |

# $\begin{array}{c} Correction \ factor \\ for \ environment \ K_U \end{array}$

Environmental influence and correction factor

| <b>Relubrication</b><br>Lubricating grease   | The grease used for relubrication should be the same as that used for initial greasing. If different greases are used, their miscibility and compatibility must be checked first.   |
|--|---|
| Relubrication interval                       | If the guide value for the grease operating life t <sub>fG</sub> is less than<br>the required operating duration of the planetary screw drive,<br>relubrication must be carried out.<br>Relubrication must be carried out at a time when the old grease can<br>still be forced out of the threaded nut by the new grease.<br>A guide value for the relubrication interval for most applications is:                       |
|  | $t_{fR} = 0.5 \cdot t_{fG}; t_{fG} < t_{fE}$  |
|  | t <sub>fR</sub> h<br>Guide value for relubrication interval in operating hours<br>t <sub>fG</sub> h<br>Guide value for grease operating life in operating hours<br>t <sub>fE</sub> h<br>Required operating duration in hours.   |
| Relubrication quantity                       | The relubrication quantity is approximately 50% of the initial grease quantity. Relubrication should be carried out wherever possible with several partial quantities at various times instead of the complete quantity at the time of the relubrication interval.  |
| Influence of grease<br>on friction behaviour | During commissioning and relubrication, the coefficient of friction<br>increases temporarily due to the fresh grease. After a short<br>running-in period, however, the coefficient of friction returns to<br>its original lower value.<br>The friction behaviour is determined significantly by the charac-<br>teristics of the grease used. The consistency and base oil viscosity<br>serve as approximate guide values. |

## Buckling

### Permissible compressive force

If the spindle of the planetary screw drive is subjected to compressive load, the design must be checked in relation to buckling.

The maximum permissible compressive force is dependent on:

- the nominal diameter of the spindle
- the free unsupported length
- the axial operating load.

The permissible compressive force  $F_{k per}$  that can act in an axial direction on the spindle of the planetary screw drive is calculated as follows:

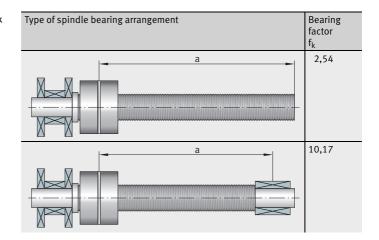

$$F_{k \text{ per}} = \frac{f_k \cdot d_0^4}{a^2} \cdot 10^4$$

 $\begin{array}{ccc} F_{k\,per} & N \\ Permissible compressive force \\ f_k & N/mm^2 \\ Bearing factor, see table \\ d_0 & mm \\ Nominal diameter of spindle \\ a & mm \\ Free spindle length. \end{array}$ 

The calculated values are theoretical values. The actual permissible compressive force on the spindle of a planetary screw drive may deviate from the calculated values as a result of component tolerances.

#### Bearing factor f<sub>k</sub>

## **Critical speeds**

# Critical and permissible spindle speed

The rotating spindle causes vibration of the planetary screw drive supported by bearings due to deflection and eccentricities as a result of tolerances. If the excitation frequency reaches the natural frequency of this system, resonance occurs that can cause damage to the planetary screw drive and the surrounding parts.

In order to prevent this, a permissible spindle speed  ${\sf n}_{per}$  is defined that is at least 20% below the natural frequency of the system.

The critical spindle speed  $n_{\rm c}$  corresponds to the natural frequency of the system and is dependent on:

- the free spindle length
- the spindle diameter
- the type of spindle bearing arrangement
- the bearing rigidity.

This critical spindle speed  ${\rm n_c}$  and the permissible spindle speed  ${\rm n_{per}}$  are calculated as follows:

$$n_{c} = \left(8 \cdot 10^{6} \cdot \frac{d_{0}^{0.95}}{a^{1.73}}\right)^{k_{1}}$$

 $n_{per} = 0.8 \cdot n_c$ 

 $\begin{array}{ccc} & \min^{-1} & \\ Critical spindle speed & \\ k_n & \min^{-1} \cdot mm \\ Factor dependent on the type of spindle bearing arrangement, see table \\ d_0 & mm \\ Nominal diameter of the spindle, see dimension table \\ a & mm \\ Free spindle length & \\ n_{per} & \min^{-1} \\ Maximum permissible spindle speed. \end{array}$ 

ļ

The calculated values are theoretical values. The actual critical and permissible spindle speeds of a planetary screw drive may deviate from the calculated values as a result of component tolerances.

#### Bearing factor kn

## Drive and holding torque

The drive torque is calculated as follows:

The drive torque of the motor is converted to an axial thrust force by the kinematics of the planetary screw drive. The decisive parameters here are the system friction and the system pitch.

# $M_a = \frac{F \cdot P}{2 \cdot \pi \cdot \eta} \cdot 10^{-3}$

**Drive torque** 

 $\begin{array}{ccc} M_a & Nm \\ Drive torque (against the load direction) \\ F & N \\ Axial force \\ P & mm \\ System pitch, see dimension table \\ \eta & \% \\ Efficiency of conversion of rotational motion into a longitudinal motion, see dimension table. \\ \end{array}$ 

**Holding torque** Planetary screw drives are not self-locking. This means that, in order to hold a load at a precise position, a minimum torque known as the holding torque is required.

|                                 |   |                |

**Features** Planetary screw drives convert rotational motion into longitudinal motion. As a result of their internal design, very small pitch values can be achieved, which means that high axial forces can be generated with relatively low drive torques. Due to the large reduction ratios, no additional gearboxes are required and smaller motors can be used.

Planetary screw drives are available in various sizes and optionally with matching Schaeffler bearing KITs.

**Design** The main components of a planetary screw drive are a threaded spindle, threaded nut and planet rollers, *Figure 1*. The threaded nut contains planet rollers arranged parallel to the axis that roll in planetary motion without axial displacement about the threaded spindle during rotation of the threaded spindle and thus give axial displacement of the nut. Due to the rolling conditions, the system pitch is not identical to the pitch of the threaded spindle.

Figure 1 Design of a planetary screw drive

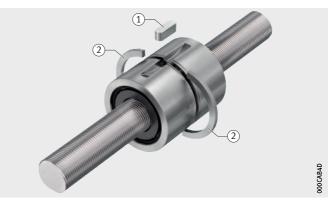

| Advantages   | <ul> <li>With their specific characteristics, planetary screw drives fill the gap between roller screw drives and ball screw drives.</li> <li>They are thus the ideal solution for numerous applications.</li> <li>The specific characteristics include: <ul> <li>very economical drive</li> <li>high axial load carrying capacity due to the large number of rolling contacts</li> <li>facility for preloading clearance-free</li> <li>very small pitch values (&lt; 1 mm)</li> <li>very smooth running, due to the lack of rolling element return</li> <li>simple, robust design</li> <li>very high performance density</li> <li>high reliability and operational security.</li> </ul> </li> </ul> |
|--|--|
| High performance density and<br>load carrying capacity | Planetary screw drives are characterised by a very high performance<br>density. Force is transmitted via the flanks of the rollers, spindle and<br>nut. Due to the large number of contact points, a very high axial load<br>carrying capacity is achieved.  |
| Economical drive                                       | Due to the small pitch, it is possible to achieve very high axial forces<br>using low drive torques and without a gearbox. The planetary screw<br>drive from Schaeffler can be used not only to give electrically driven<br>actuators with a high performance density, long operating life and<br>low maintenance requirements but also allows the use of econ-<br>omical motors. Integration of the electric drive can be achieved very<br>easily by means of a feather key connection on the outside diameter<br>of the spindle nut.   |

Areas of application Due to the high performance density, planetary screw drives are extremely suitable as force actuators and offer the potential for replacing hydraulic axes by energy-efficient electromechanical drives.

Possible areas of application can be found in radial pressing tools, in the automation of buildings and processes, as a replacement for hydraulic systems in machine building, in servo table presses and riveting machines, in closing cylinders for plastics injection moulding machines and in the control of maritime drive units. There are also areas of application as actuators in the automotive industry.

**Threaded nuts** Planetary screw drives are supplied by Schaeffler with a cylindrical nut, *Figure 2*. The feather key secures the threaded nut against rotation due to the occurring frictional torques in the housing. The spacers limit the preload when axially securing the nut in the adjacent construction and are matched to the use of the threaded spindle supplied.

Feather key
 Spacers

*Figure 2* Cylindrical nut

| Spindle bearing arrangement | The threaded spindle of a planetary screw drive can be ordered with the following spindle ends: |
|-----------------------------|---|
|                             | spindle ends with bearing seats for locating bearings with                                      |

- drive journals (type A) and non-locating bearings (type M), see dimension table
- without bearing seats, but with the spindle ends cut and chamfered.

# **Bearing KITs** Bearing KITs can be supplied to match the bearing seat and load carrying capacity of planetary screw drives. All the rolling bearings in the KITs are sealed and greased for life.

The bearing KITs must be ordered specially, see table and page 28.

When using the locating and non-locating bearing KITs, the following restriction on the axial load must be taken into consideration:

PWG05: 
$$P_a \leq 0,25 \cdot C$$

PWG09: 
$$P_a \leq 0,33 \cdot C$$

 $\blacksquare~$  PWG12, PWG15, PWG20 and PWG25:  $\mathrm{P_a}$   $\leq$  0,5  $\cdot$  C

For PWG12 to PWG25, where higher axial forces are present, please consult Schaeffler.

### Locating bearing KIT

# A locating bearing KIT comprises the following components, *Figure 3*:

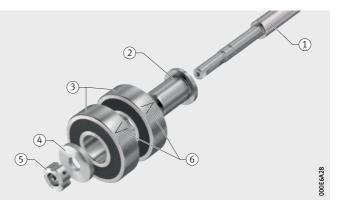

- 2 angular contact ball bearings of a tandem design for bracing in an O arrangement
- 1 sleeve matching the diameter
- 1 locknut and 1 thrust washer for preloading the bearing unit.

#### Threaded spindle

Components of the locating bearing KIT: ② Sleeve ③ Angular contact ball bearing ④ Thrust washer ⑤ Locknut ⑥ Markings form an "O"

> Figure 3 Locating bearing KIT

> > Mounting

Sequence of work operations in the mounting of a locating bearing KIT:

- The sleeve is mounted on the matching seat on the shaft.
- The two angular contact ball bearings are mounted consecutively on the sleeve such that the markings on the bearing outer rings form an "O".
- The thrust washer is slid onto the shaft.
- The locknut is then screwed into place on the shaft and the retaining pin of the locknut is tightened. The specified tightening torques must be observed, see table.

In order to ensure suitable axial preload of the bearings in an O arrangement, the locknuts must be tightened to the specified tightening torque.

| Size  | Locknut | Tightening torque | S             |
|-------|---------|-------------------|---------------|
|       |         | Locknut           | Retaining pin |
|       |         | Nm                | Nm            |
| PWG05 | M5×0,5  | 2                 | -             |
| PWG09 | ZM06    | 3                 | 1             |
| PWG12 | ZM08    | 5                 | 1             |
| PWG15 | ZM10    | 8                 | 1             |
| PWG20 | ZM12    | 10                | 1             |
| PWG25 | ZM17    | 19                | 3             |

#### Locknuts and tightening torques

### Non-locating bearing KIT

A non-locating bearing KIT comprises the following components, *Figure 4*:

- 1 deep groove ball bearing
- 1 retaining ring
- 1 sleeve for matching the diameter (only for PWG05).

1 Threaded spindle

Components of the non-locating bearing KIT: (2) Sleeve (only for PWG05) (3) Deep groove ball bearing (4) Retaining ring

*Figure 4* Non-locating bearing KIT

Mounting

Sequence of work operations in the mounting of a non-locating bearing KIT for PWG05:

- There must be a slight interference fit between the sleeve and the shaft and between the bearing inner ring and the sleeve.
- The sleeve is pressed onto the matching seat on the shaft.
- The deep groove ball bearing is pressed onto the sleeve.
- The retaining ring is then mounted in the groove on the end of the shaft.

Sequence of work operations in the mounting of a non-locating bearing KIT for PWG09 to PWG25:

- The deep groove ball bearing is pressed onto the matching seat on the shaft.
- The retaining ring is then mounted in the groove on the end of the shaft.

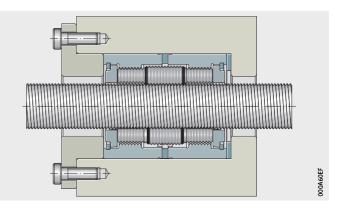

### Setting the preload

Planetary screw drives must be set clearance-free. For this purpose, there is a spacer of a matched width between the two halves of the nut. The system is set clearance-free once it is mounted in the adjacent construction. By means of suitable machine components, both nut halves must be axially pressed against each other with a minimum preload force, see table.

### Preload forces for threaded nuts

| Size  | Preload force |
|-------|---------------|
|       | Ν             |
| PWG05 | 250           |
| PWG09 | 500           |
| PWG12 | 550           |
| PWG15 | 700           |
| PWG20 | 800           |
| PWG25 | 900           |

The axial location of the nut can be carried out, for example, by means of a classic bearing cover, *Figure 5*, or by a bearing cover with a threaded ring, *Figure 6*, page 27. In this case, the threaded ring facilitates easier and more precise setting of the preload.

*Figure 5* Axial location of the nut by classic bearing cover

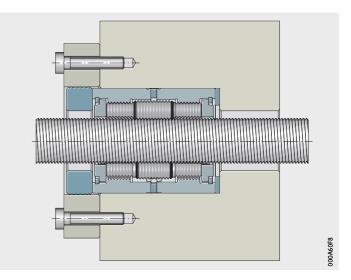

Figure 6 Axial location of the nut by bearing cover with threaded ring

The feather key and spacers are fixed and held in place in the delivered condition by a transport securing device, *Figure 7*. The transport securing device must be removed before mounting.

| Design and  |   |
|---|---|
| safety guidelines<br>Design<br>of the adjacent construction | Planetary screw drives are designed for the support of high axial<br>loads. Transverse forces and tilting moments increase the internal<br>forces in the nut and thereby lead to a significant reduction<br>in operating life. In order to prevent transverse forces and tilting<br>moments, it is essential that the following specifications are<br>observed in the design of the adjacent construction.  |
| Support and loading   | The end faces of the nut in the planetary screw drive must be fully supported. When determining the locating diameter, the inside diameter D <sub>i</sub> of the nut must be observed, see dimension table. In order to utilise the full performance capability of the planetary screw drives, we recommend that ground steel washers are used with light metal or cast housings. The steel washers improve the application and distribution of forces in the housing. Planetary screw drives are suitable for the transmission of axial forces only. Radial force components must be supported and must not be directed through the nut. If the threaded spindle is subjected to compressive load, it must be ensured that the maximum permissible compressive force is not exceeded, see page 14. Otherwise, buckling of the spindle may occur. In case of doubt, tensile load must be applied instead. |
| Alignment   | Misalignments of any sort must be avoided, since they induce<br>internal forces that apply load to the rolling contact in addition to<br>the axial force and thus reduce the operating life.<br>The geometrical and positional tolerances of the locating bore<br>as well as the running accuracy of the nut housing relative to<br>the spindle axis must be checked, see page 30.  |
| Sealing   | Dust draws the base oil out of the grease and liquid media wash<br>out the grease. As a result, these contribute to a reduction in<br>operating life, due also to their abrasive and aggressive behaviour<br>respectively.  |
| !   | Under adverse environmental conditions such as dust or liquid<br>media, planetary screw drives must be protected against the ingress<br>of contamination by means of a cover. Bellows or telescopic tubes<br>are suitable as covers.  |
| Cleanliness   | Check the holes and locating edges for burrs. Any burrs present must be removed.  |
| !   | The adjacent construction must be clean. Contamination will impair the accuracy and operating life of the planetary screw drive.  |

### Accuracy Tolerances of the adjacent construction

When designing the adjacent construction of a planetary screw drive, it is absolutely essential that the tolerance specifications for the complete system, for the adjacent construction of the threaded nut and for the bearing seating surfaces are observed.

Complete system

The complete system is subject to tolerance specifications for perpendicularity and parallelism, *Figure 9*. The tolerance specifications for parallelism are particularly valid in conjunction with guideways.

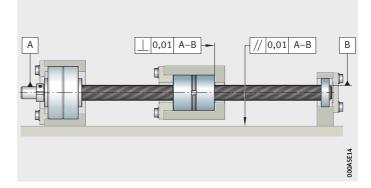

Figure 9 Tolerances of complete system

The nut must never be braced in the travel range near the bearing positions.

Adjacent construction of the threaded nut The adjacent construction of cylindrical nuts is subject to tolerance and surface specifications, *Figure 10*.

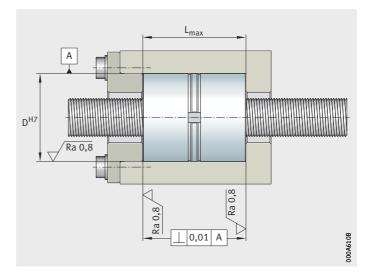

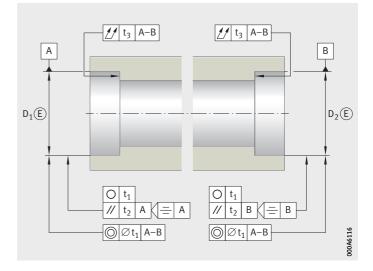

Figure 10 Tolerances of adjacent construction of cylindrical nut

# Bearing seating surfaces for locating bearing arrangement

For the accuracy of the bearing seating surfaces in a locating bearing arrangement, geometrical and positional tolerances must be observed, *Figure 11* and table.

 $t_1 = \text{roundness} \\ t_2 = \text{parallelism} \\ t_3 = \text{axial runout of abutment shoulders}$ 

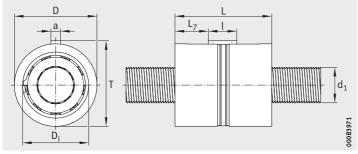

Guide values for the geometrical and positional tolerances of bearing seating surfaces

When using planetary screw drives in combination with the locating and non-locating bearing KITs, the restriction on the axial load must be taken into consideration, see page 23.

Locating bearing (type A)

Non-locating bearing (type M)
